#### MINIMON FIX

The program *MiniMon* (Antic, April 1989), will not run on my Atari 1200XL as written. For an easy fix, change Line 1140 in Listing #1, MINIMON.BAS. The seven **boldfaced** numbers below are the only ones to change:

1140 DATA 204096132205032**066**2 422011601440020731281620001421820 02164205096132205032**245**241164205 096125155

Now MINIMON.BAS will create a machine language file called MINIMON.EXE that will work on an 800 or 1200XL. The new version will not work an an XL/XE without a translator.

Paul Alhart Lompoc, CA

Antic doesn't have a working 1200XL to check this on, but Paul Albart has published a number of programs and Tech Tips in this magazine. — ANTIC ED

#### DO 8-BITS SWIM?

I am presently the meet manager of our local swim club. Our club just yesterday finished hosting the Provincial Championships and I found the paperwork very time-consuming. I'd like to find a program I can use on my 130XE, one that will store information on the swimmers, seed the swimmers, produce time cards, and print the information in a program format. The only such program I can find is for IBM PCs. Is there one I can use on my Atari 8-bit?

Jerry Parsons Gander, Newfoundland, Canada

A spreadsheet program such as SynCalc could hold the information on swimmers, do some mathematical figuring for you, and print reports of the information. Talk to members of your local users group about available spreadsheets—or even finding a BASIC programmer who could write a custom program designed specifically for your set-up. — ANTIC ED.

#### **BEGINNER'S BLUES**

Sometimes I feel like a man sitting in a well-equipped garage feeling frustrated because I don't know how to use the tools. That's my situation with these cotton-pickin' computers and magazines I've picked up.

Don't get me wrong. . .since getting an Atari XE Game System for Christmas in '87 there's been a lot of time spent at the keyboard—but the potential is so much greater than the performance. I started reading *Antic* in early 1988, but I need the elementary stuff to lead the way, and it's been hard to find. I would like to know more about the different BASICs, where I can find a small business inventory program, how to get a word processor that fits me.

I hope you're thinking of us newcomers who aren't in school any longer. Give us a helping hand so we can catch up with you.

Bob White Ferndale, MI

It's always bard to cover the needs of all our readers. Many of the topics you're interested in have been covered in previous issues, and most back issues are still available. If you don't know what issue you want, the ANTIC ONLINE Index on CompuServe is the most complete resource we can offer. You can search for articles, reviews and programs by title, subject, date and author. Very often, the complete text of the article is included in the index itself.

Users groups are also an excellent source of help, and there are several active users groups in Michigan who produce a large joint newsletter, the Atari Interface Magazine. You can write them at Unicorn Publications, User Group Information, 3487 Braeburn Circle, Ann Arbor, MI 48108. Send them your address, phone number, and the kind of computer you own, so they can link you up with the appropriate group.—ANTIC ED

continued on next page

#### DOS, 800 & XF551

It was with great sadness that I read your article on DOS-XE (March, 1989). I eagerly awaited Atari's new DOS, only to find out that it would not work with my old reliable 800. Playing around with the cartridge door switch so I can use SpartaDOS X does not appeal to me, either.

The Antic Arcade seems to say that SuperDOS 5.0 is compatible with all Atari 8-bit computers. Will it let me take advantage of all the XF551's capabilities?

Thomas Andrews Manlius, NY

According to Arcade Manager Charles Cherry, SuperDOS 5.0 does work with the 800 and will give you full control of the XF551. — ANTIC ED

#### **ATARIAN FRIENDS**

I am the computer coordinator in the Lower School at the Wilmington Friends School. Fortunately, eight years ago the very wise principal of our school purchased four Atari 800 computers. Since then we have designed a curriculum around computer programming and word processing. The Atari computer is so easy for young children to program in graphic colors that we begin first graders designing and programming their own patterns. We continue programming through the fourth grade, with students strengthening their ability to plan a project.

Presently we have four 800s, two 800XLs, and 23 65XE computers. With the reasonable price of the system, many parents have also been able to get Ataris for their homes. I have prepared many lesson plans for teachers to use with BASIC on the Atari. It distresses me to see Atari systems take the back seat in conferences, catalogues, and everyday conversation.

Bertie Toler Wilmington Friends School 101 School Road Wilmington, DE 19803

#### **CELEBRITY REVIEW**

In my review of **Celebrity Cookbook**, published in the February 1989 **Antic**, I noted two problems with the program—quirky joystick response, and an inability to print the recipes, despite a very generic printer driver.

Well, I wrote the company, and they did send me a fresh copy that fixed these bugs. It was six weeks in arriving, perhaps due to having moved their offices from California to Maryland about that time. But the support *was* there for me, so I wouldn't hesitate to recommend the product.

David Merrihue Daly City, CA

Celebrity Cookbook (\$29.95) is available from U.S.A. Media, 7810 Malcolm Road, Clinton MD 20735. (301) 868-5494. — ANTIC ED

#### FROM DEBUGGING TO BUG SPRAY

I would like to start an Atari Farmer's and Gardener's user group. Anyone who uses an Atari 8-bit to help them with their gardening or farming is welcome to join. I would like to issue a disk full of useful programs, if we can accumulate enough. We are particularly interested in artificial intelligence applications for the purpose of sorting out plant nutrient requirements, programs to track nutrient usage, or anything else that would help with the task of growing food. This includes hardware interfacing with real world sensors, etc.

Anyone interested should drop us a letter with a self-addressed stamped envelope, and we'll let you know how it's going. The Atari 8-bit is the most cost-effective computer around. Let's get on the ball and see if we can apply it to the much needed job of producing wholesome food.

GROMOR-SYSTEMS

Lee Jones Rt. 1 Box 76-B Pleasantville, TN 37147-9801

#### ATARIWRITER DRIVERS

I have a problem with the subscript and superscript commands in AtariWriter. The printer goes into subscript or superscript mode, but won't come out, so everything is printed in tiny print slightly above or below the normal print line. I have an Epson LX-80 printer. Is there anything I can do to fix the problem?

K. Helton Sacramento, CA

The Antic Arcade's **Printer Driver Construction Set** (APO131, \$19.95) will let you set up a special driver file that will "make your AtariWriter cartridge compatible with any printer." — ANTIC ED

#### **DRIVE NEEDS DOS**

We have an Atari 800XL and a disk drive, and are thinking of subscribing to your disk magazine. Do you need DOS to play the disks?

J.E. Barclay Lake Havasu City, AZ

DOS stands for Disk Operating System, and as the name suggests, you need some sort of DOS to use a disk drive. Fortunately, the Antic Monthly Disk always comes with Atari DOS 2.0 on it—all you need to do is put the disk in the drive and turn the computer on, and the disk menu will appear. — ANTIC ED

Antic welcomes your feedback, but we regret that the large volume of mail makes it impossible for the Editors to reply to everyone. Although we do respond to as much reader correspondence as time permits, our highest priority must be to publish I/O answers to questions that are meaningful to a substantial number of readers.

Send letters to: Antic I/O Board, 544 Second Street, San Francisco, CA 94107.

\$99.95

#### JUST RELEASED! "SUPER ARCHIVER II"! Thinks

(for ATARI 1050 drives)

NOW! COPYS all ENHANCED DENSITY programs plus retains all of the features of our World Famous SUPER ARCHIVER! (see below). Allows you to COPY or CREATE single or ENHANCED density protection schemes (including PHAN-TOM SECTORSI). Completely automatic; compatible with the BIT-WRITERI; the ULTIMATE BACKUP/PROGRAMMING device! Only \$99.95 plus \$4 S/H/I NOTICE! If you already own a SUPER ARCHIVER!, you can upgrade to a SUPER ARCHIVER! If for only \$29.95 plus \$4 S/H/I (disk only - no additional hardware required).

#### THE "SUPER ARCHIVER"!" \$69.95 \$69.95 (for ATARI 1050 drives)

The new SUPER ARCHIVER, obsoletes all copying devices currently available for the ATARI 1050! It eliminates the need for Patches, PDB files, Computer Hardware, etc. Copies are exact duplicates of originals and will run on any drive; without exaggeration, the SUPER ARCHIVER is the most powerful PROGRAMMING/COPYING device available for the 1050! Installation consists of a plug-in chip and 6 simple solder connections. Softwares included

- TRUE DOUBLE DENSITY
- **ULTRA-SPEED** read/write
- FULLY AUTOMATIC COPYING
- SUPPORTS EXTRA MEMORY SCREEN DUMP to printer TOGGLE HEX/DEC DISPLAY
- SECTOR OFTRACK TRACING AUTOMATIC DIAGNOSTICS
- DISPLAYS HIDDEN PROTECTION
- ADJUSTABLE/CUSTOM SKEWING
- AUTOMATIC SPEED COMPENSATION
- AUTOMATIC/PROGRAMMABLE PHANTOM SECTOR MAKER
- ARCHIVER/HAPPY ARCHIVER COMPATIBLE
- BUILT-IN EDITOR reads, writes, displays up to 35 sectors/track
- BUILT-IN CUSTOM FORMATTER
- up to 40 sectors/track

   BUILT-IN DISASSEMBLER
- . BUILT-IN MAPPER up to 42 sectors/ track
- DISPLAYS/COPIES Double Density **HEADERS**
- AUTOMATIC FORMAT LENGTH
- CORRECTION SIMPLE INSTALLATION

The SUPER ARCHIVER is so POWERFUL that only programs we know that can't be copied are the newer ELECTRONIC ARTS and SYNFILE/SYNCALC (34 FULL sectors/track). If you want it ALL . . . buy the "BIT-WRITER"! also . . . then you'll be able to copy even these programs! Only \$69.95 plus \$4 S/H/I.

#### "BIT-WRITER"! \$79.95

The Super Archiver "BIT-WRITER"! is capable of duplicating even the "uncopyable" EA and SYN series which employ 34 FULL sectors/tracks. "BIT-WRITER"! is capable of reproducing these and FUTURE protection schemes of non physicially damaged disks. PLUG-IN circuit boards and 4 simple solder connections. The "SUPER ARCHIVER with "BIT-WRITER"! is the ultimate PROGRAMMING/COPYING device for Atari 4050's. EXACT DUPLICATES of originals are madel Copies run on ANY drive. Must be used with Super Archiver. Only \$79.95 plus \$4 S/H/I.

#### "ULTRA SPEED PLUS" \$69.95 \$69.95

Imagine a universal XL/XE Operating System so easy to use that anyone can operate it instantly, yet so versatile and powerful that every Hacker, Programmer and Ramdisk owner will wonder how they ever got along without it! Ultra Speed Plus puts unbelievable speed and convenience at your fingertips. Use ANY DOS to place an ULTRA SPEED format on your disks, boot any drive (1-9) upon power-up, format your RAMDISK in Double Density, activate a built-in 400/800 OS for software compatibility, plus dozens of other features too numerous to mention! Below are just a FEW features you'll find in the amazing OS:

- ULTRA Speed SIO for most modified drives ULTRA Speed is toggleable Boot directly from RAMDISK Special timer circuits not required for 1 or 2 Meg upgrade Background colors adjustble Reverse use of OPTION key

- Cold-start without memory loss Built-in floppy/disk configuration editor (1-9)
- Built in RAMDISK configura-tion editor (1-9)
   RAMDISK exactly duplicates floppy drive so sector copy-ing and sector editing are now possible
   Built in MiNI Sector Copter Toggle SCREEN OFF for up to 40% increase of processing speed.
- - speed.
     Toggle internal BASIC

- DOUBLE DENSITY RAMDISK capable
   Entire MEMORY test that pinpoints defective RAM chip
   Boot any drive (1-9) upon power-up or cold-start
   Supports memory upgrades up to TWO MEGABYTES
   THREE Operating Systems in one (XLXE, 400/800, ULTRA SPEED PLUS)

#### "XF551 ENHANCER!"

The XF551 Atari drive is a fine product with one major flaw...it writes to side TWO of your flopping disks BACKWARDS. This causes read/write incompatibility problems with all other single sides drives made for Atari such as Indus. Trak, Rana, Percom, Astra, Atari 1050, Atari 810, etc. Add the XF551 ENHANCER to the new XF551 drive and your problems are over! This device will restore 400% compatibility while retaining original design qualities of Atari's super new drive. The XF551 ENHANCER is a MUST for all XF551 Owners. Installation is simple. Only \$29.95 plus \$4 S/H/I. DEALER/DISTRIBUTOR/USER GROUP Discount available call for info. PHONE Orders - MASTER CARD, VISA MAIL - Money Orders, Checks

#### 80 Column Word-Processor!

Easy to use, very powerful, and NO ADDITIONAL HARDWARE required! Works with TV or Monitor! This "DISK ONLY" 80 Column Word-Processor is simple to use while offering numerous features such as:

- Completely Menu driven
- Self contained DOS
- Complete Text formatting
- **Built in Printer Drivers**
- Page numbering Justify and Endfill
- **High Speed Cursor**
- Dictionary

80 COLUMNS ON THE SCREEN!

- Insert and Delete
- Search Mode View only mode
- **Memory Statistics**
- Alternate Output
- Change screen Colors,
- borders, luminesce Mouse compatible

One expert has compared 40 domestic and foreign word-processors and concluded that the RICHMANS 80 Column Word-Processor is the best! Only \$39.95 plus \$4 S/H/I. (64K required).

#### THE "QUINTOPUS!" \$39.95 \$39.95

The "QUINTOPUS!" is an inexpensive device that provides a tremendous amount of convenience while eliminating the problems associated with the encless "daisy-chaining" of peripherals (eg: drives, interfaces, printers, modems, cassettes, etc.). The "QUINTOPUS!" is an I/O port expander that converts a single I/O output/input into five additional outputs/inputs. Instead of daisy-chaining all of your peripherals (which often times results in passing a signal through 30 feet or more of cable!), the "QUINTOPUS!" allows each device to be connected directly to the computers through only three or four feet of cable. This is particularly useful when attempting to use ULTRASPEED or WARPSPEED data transfer rates. The "QUINTOPUS!" also provides the "extra" I/O ports often needed to connect devices not having daisy-chaining capabilities. Cable resistance and compacitance are greatly reduced thereby significantly improving the opportunity of accurate data transfers! Only \$39.95 plus \$4 S/H/I.

#### THE "QUINTOPUS!" \$59.95 (with SWITCHABLE PORTS!)

a switch! Only \$59.95 plus \$4 S/H/I.

This Deluxe version of the "QUINTOPUS!" has all of the above features with the additional benefits of two SWITCHABLE PORTS! This means you can connect two computers to one printer or two printers to one computer; you can switch in a computer/printer combination and while you're printing out a long document, switch in a second computer to access a modem, disk drive, cassette deck, etc! Switch multiple combinations of peripherals

#### LIMITED SPECIALS!

or computers without the hassel or re-arranging I/O cables . . . . simply flip

Previously we listed these products under our FIRESALE ad but many of our customers feared that the software items might be smoke or water damaged. They're NOT! All of the items listed below are BRAND NEW...only their literature or packing may have slight cosmetic imperfections. All items are fully warrantied! Quantities are limited! No rainchecks!

	NORMALLY	LIMITED SPECIALS
1. PILL (without case)	\$ 70	\$ 19
2. SUPER PILL (without case)	80	22

# Machine Language Stringer

Save 7 seconds on each BASIC subroutine.

By Andy Barton

Machine Language Stringer takes machine language object code and converts it into string format for use in your own BASIC programs. This BASIC program works on Atari 8-bit computers with at least 48K memory and disk drive.

ost machine language routines in BASIC programs are in the form of string data. This is done partly because strings take up less space than numerical DATA statements. They frequently don't need to be POKEd into a memory location.

When I tried translating a machine language routine in one of my programs into string format, I discovered the best reason for using strings. The string format virtually eliminated the seven seconds used to READ the 144 bytes of data and POKE them onto page 6. I was sold. I dearly hate to wait for slow computers.

I developed Machine Language Stringer to do the near-impossible manual task of taking the object code file of a machine language program (the executable code) and converting it into a set of BASIC program lines that will produce the proper string data.

#### **GETTING STARTED**

Type in Listing 1, STRDAT.BAS, and check it with TYPO II. Be sure to SAVE a copy to disk before you RUN it.

If you have difficulty typing the special characters in Line 460, don't type them in. Instead, type Listing 2, check it with TYPO II and SAVE a copy. When you RUN Listing 2, it creates these hard-to-type lines and stores them in a file called LINES.LST.

To merge the two programs, LOAD "D:STRDAT.BAS" and then ENTER "D:LINES.LST." Remember to SAVE the completed program before you RUN it.

When you RUN the program, you will be asked for the object file name. If you forget the "D:" or the name is not found you will be asked again.

Next you are asked for a starting line number. Be sure you choose one that will not overlap lines in your BASIC program or in this one.

Finally, you are asked for a name for the machine language string (maximum of 2 characters). The program will add a numerical extender to this name, starting with 1. The program will now go about the business of reading the object file and building the BASIC line(s) that will be incorporated into this program using Atari's forced read mode.

When the program is done, there are three more steps for you to take to incorporate the string into your basic program.

1. LIST the new lines to a disk/cassette file, for example:

LIST "D1:YOURPRG.STR",1000,1005.

2. LOAD your BASIC program and ENTER the string data file, for

example:

ENTER "D1:YOURPRG.STR".

3. Make a USR comand to run the ML string.

#### **PROGRAM NOTES**

There are two numbers that cannot be displayed in a string—34 and 155. 34 is ASCII for a quotation mark and 155 is ASCII for a carriage return (return key). This program handles this problem by creating a separate line that inserts the number into its proper place in the string, for example:

1001 ML1\$(72,72) = CHR\$(155).

There are two types of machine language programs, ones that are fully relocatable and ones that are fixed at a particular memory location. Jump (JMP) and jump subroutine (JSR) comands use absolute rather than relative addressing and thus require the program to be at the specific location to which it was assembled.

Machine Language Stringer accommodates this by creating a final BASIC line which provides a brief machine language string to move the string data to the memory location indicated by the object file, for example:

1006 X = USR(ADR(''hh. . .'')), FROM, TO, NO. BYTES)

This line is provided regardless of which type of machine language program you wrote. If your program is fully relocatable, this line can be deleted.

It is possible to create a program that is loaded into two or more separate memory locations. For example, a section of subroutines could be fixed onto page 6 and the main program could be totally relocatable. Machine Language Stringer accomodates this by using the numeric extender mentioned above. Each time a new load address is indicated in the object file, the extender is increased by one, creating a new string name. Each string is provided with its own loader.

As mentioned above, for a program to be relocatable it cannot use abso-

lute addressing with jump instructions. I have found no way around this problem with subroutines other then placing them on Page 6 or some other safe, fixed location.

However, there are two tricks I have discovered for JMP instructions. The problem arises when I would use a branch instruction, but find that its range (126 bytes) was too short so I would be forced to use a JMP instrution. The first crude but effective solution involves setting up intermediate branches to one or more areas within range, but outside the flow of the program. Here is an example:

LOOP LDY #0 PART1 LDA (\$D0),Y

BEQ PART1

BNE PART2 ;BRANCHES

;OVER

BP1 BCS LOOP ;INTER-

;MEDIATE ;BRANCH

PART2 ASL A

SEC

;SET CARRY

;TO

BCS BP1 ;FORCE A

;BRANCH

The second solution is more versatile, using the indirect jump instruction JMP(XXXX). It involves passing the address of the relocateable ML string to the ML program in BASIC's USR command. The ML program then figures the relative distance from the start of the program to the targeted instruction, adds this to the starting address of the string and saves the results on page 6 for the JMP(XXXX) to use. Here are two examples, first in BASIC:

X = USR(ADR(ML\$), ADR(ML\$))

In ML, this would be: IJP1 = \$600 ;SAFE

;STORAGE

;FOR

IJP2 = \$602; INDIRECT

;JUMP

;ADDRESS

START \* = \$5600

PLA

PLA ;HI BYTE OF ;ADDRESS OF ML

STRING

TAX

PLA ;LOW BYTE OF

;ADDRESS

TAY ;SAVE IF MORE ;THEN ONE JUMP

;TARGET ;NEEDED

CLC

ADC #<TARG1-START

;ADD LOW BYTE :OF TARGET

;ADDRESS OFFSET

;TO ML STRING ;ADDRESS

STA IJP1

TXA

ADC #>TARG1-START

;ADD HI BYTES

STA IJP1+1

TYA ;GET LOW BYTE ;STRING ADDRESS

CLC ;FOR SECOND :TARGET

ADC #<TARG2-START

. . . :etc.

TARG1 SEC ;SOMEWHERE IN ;MAIN PROG.

. . .

JMP(IJP1)

You may have to modify the program to get it to work with character set files. This program strips the first two control characters from the file, so you would end up with 1022 instead of 1024 bytes in your character set files.

As always, whenever modifying your programs you should first make backups of the originals, in case problems arise.

Andy Barton has been a regular contributor to Antic since 1984. His machine language game, Exwall, is this month's Super Disk Bonus.

# Customizing the Atari

# **Operating System**

## **Device Handlers:**

By Bob Martin & Martin Mercorelli

The final balf of this series is for experienced MAC/65 programmers. It describes an interactive bandler that saves machine language programs as boot files. This program requires MAC/65 and OS/A+, and works on all 8-bit Atari computers of any memory size, with disk drive.

In the previous month's **Antic**, the first half of this series introduced device handlers and described how they work by creating two simple handlers. This final installment describes the creation and operation of MAKE-BOOT, a more sophisticated device handler.

The MAKEBOOT handler lets you

save object code as a boot file and convert binary load files to boot files. Before the MAKEBOOT handler can do this, however, it does something quite unique—it asks you questions.

Although almost every useful computer program prompts you for information, handlers do not. Since the CIO (Central Input/Output) uses de-

vice handlers whenever it operates, the device handlers cannot easily use CIO to prompt you for information the CIO is busy.

If we try to use the CIO while it's busy, your Atari usually—but not always—becomes confused and acts strange. This is why handlers should not use CIO for I/O to the screen or

keyboard.

The catch is that we often want to interact with a program while a handler is in use. Therefore we must use the screen or keyboard handlers directly, *without* going through the CIO.

MAKEBOOT is an example of such a handler. The MAKEBOOT program requires you to direct the handler operation and make some decisions while it's operating. Your Atari operating system has a built-in mechanism for accomplishing this.

Uses for this program include loading an alternate program into the same area occupied by DOS, or initializing your Atari before DOS is loaded. For example, you could load in the modification to the printer handler. You could use this program to produce bootable games or programs that produce a disk menu.

#### **BOOT FILES**

A boot file is a machine language program which resides on the outermost sectors of a disk. It is automatically loaded whenever you boot with that disk. On the disk, the boot file is a continuous, uninterrupted file which begins in the first sector and occupies successive sectors until the end of the file. On disk, there are no breaks between the end of one sector and the beginning of the next—and no directory.

Binary load files are machine language programs which may reside anywhere else on the disk. On the disk, a binary load file may be broken into sector-sized pieces and scattered throughout the disk. The last three bytes of each sector direct your Atari to the next sector of the file. Your Atari treats these sector links as "Continued On Sector xxx" messages.

Every time you boot a disk, your Atari checks the first six bytes of the first sector to determine what action to take next.

Byte 0, the first of these six bytes, is used as a flag. (A zero in this location denotes a boot file.) This value

is stored to DFLAGS, memory location 576 (\$0240).

Byte 1 contains the number of sectors to load, bytes 2 and 3 tell your Atari where to load the boot data (this is the "load address"), and the next two bytes tell your Atari where to go after the program starting at byte 6 is executed (this is the "initialization address").

The program starting at byte 6 is an

The
MAKEBOOT
handler
does something
quite
unique—it
asks you
questions.

initialization program and usually ends with an RTS (ReTurn from Subroutine) instruction. If there is no initialization routine, then byte 6 *must* be an RTS instruction, which is represented by a 96 (\$60).

If the initialization routine doesn't start at byte 6, then byte 6 must be a JuMP instruction, directing your Atari to the start of the initializing routine.

When the initialization program ends, the operating system jumps to the memory location given in bytes 4 and 5.

The program in Listing 1, MAKE-BOOT.M65, treats the first nine bytes of sector 1 as if it was structured as shown in *Figure 1*. This structure requires nine bytes of data on sector 1.

When a series of sectors is loaded as part of the initial boot, the sectors are loaded sequentially in memory. For example, if the initial load address is 1000, then sector 1 loads its data starting at 1000 (including the first six bytes), sector 2 loads its data starting at 1128 (there are 128 bytes per sector), etc.

This initial boot sector load is called the first-stage load. For a DOS format disk, three sectors are loaded in the first-stage load, then your Atari loads DOS.SYS, a second-stage load.

Since the boot sectors are loaded in memory sequentially, the specified load address (bytes 2 and 3) is treated as the memory location of byte 0 of sector 1, and data on the disk is calculated relative to that address. In the example, if the load address was 1000, then byte 0 of sector 1 corresponds to memory address 1000, byte 0 of sector 2 corresponds to address 1128, etc. Note that the initialization routine of the boot sectors starts at 1006, since all of sector 1 (including the first six bytes) is loaded.

#### THE LOAD FILE

Now that we've determined a way to put data on the boot disk, we need to know how data will be received from the CIO. Load files are loaded by DOS as a series of data blocks. A block can be any length, but they're typically 251 bytes long (at least in MAC/65) and preceded by two two-byte numbers. The first number is the starting address, where the first byte is stored. The second number is the ending address, where the last byte is stored.

If DOS was loading this file in memory, each byte of the block would be stored sequentially until the ending address was reached. Then it would repeat the process until all the data had been loaded.

This varies only at the start of a file and when appending files. The start of a file has two bytes of the value 255 that identify it as a load file. When one load file is appended to another, these bytes are carried over to the load data. This means that a data block is preceded by either four or six bytes,

where the first two are 255, 255.

Since each block has its own load address, data can be loaded in widely separated memory locations even for a short load file. Thus the load file doesn't necessarily have the same number of sectors as the resulting boot sector count used by the MAKE-BOOT handler.

Finally, two more addresses are used by DOS as vectors for load file execution—the initialization address loaded to INITAD, memory location 738 (\$02E2); and the run address loaded to RUNAD, memory location 736 (\$02E0). The latter is executed after the file is completely loaded and the former is executed as soon as a new address is loaded to INITAD.

Generally these addresses should correspond to the boot sector run address of bytes 4 and 5 and the initialization routine starting at byte 6. Both addresses are loaded as any other data from a load file (e.g. as a two-byte data block).

#### **HOW IT WORKS**

In Part 1 of this series, we discussed three steps of adding a new handler:

- 1. Write the program for the handler.
  - 2. Set up the Handler Table.
- 3. Make an entry in the Handler Address Table.

In step 1, the routines that comprise the handler are on lines 5000-8600.

The open routine (BOPEN, lines 5185-5480) sets the initial values of the variables used in the program and checks to make sure you still want to proceed. It also writes zeros into as many sectors as you want, starting with sector 1.

The close routine, line 7130-7495, writes the last sector to the boot disk. Then it takes the actual sector count, the run address and the initialization address, and asks you if you want to add these to the boot disk (the first nine bytes of sector 1).

The PUT BYTE routine (BPUT), line 6925-7085, receives all the data from the load file. Most subroutines

in this program support the PUT BYTE handler. This routine first stores the byte from the CIO and then checks to see if it's part of the first six bytes of the load file. If so, subroutine FSTSIX checks for a load file and lets you set the sector count, load address, run address and initialization address.

Data after those first six bytes is either program data stored in a 128-byte buffer before being written to the boot disk, or load information extracted by the subroutine LDINFO. This subroutine compares the starting address of the load file with the corresponding boot sector load address and calculates the location of the next block on the boot disk. If a load file address is lower than the specified boot disk load address, an error message is issued and the CIO returns control to you.

The data in memory locations 736-739 (\$02E0—\$02E3) are stored in the variables RUNADR and INTADR. In the CLOSE routine, you can add these values to their respective positions in sector 1.

The handler for the GET status routine is also used as the general exit routine for all handler routines. This large program needs an internal stapasses error code 146 back to the CIO.

The handler in lines 5035-5065 is not very complicated. Each address is represented by the address-minus-one of each routine and is in the order given in *Figure 1* in part one of this series from last month's **Antic.** 

Step 3 (lines 440-630) makes an entry into the Handler Address Table, finding an empty spot in the Handler Address Table and adding the ASCII code for "B" followed by the address of the Handler Table. That's the same routine used in the NULL handler.

#### I/O WITHOUT CIO

The I/O subroutines for the MAKE-BOOT handler run from line 7505 to the end of the program. The first one reads and writes sectors to the boot disk. It doesn't use the resident disk handler (DSKINV) but instead uses the serial bus I/O utility vector (SIOV) and lets you write without writeverification, greatly speeding the process of writing to disk.

To use SIOV, we must fill in all the values of the Device Control Block (DCB) from memory locations 768—779 (\$0300—\$030B). But for this application only four bytes of data are variable. To read a sector, set the fol-

Label	Memory Location	Value
Read a Sector		
DCOMND	770 (\$0302)	82 (\$52)
DSTATS	771 (\$0303)	64 (\$40)
Write a Sector		
DCOMND	770 (\$0302)	87 (\$57)
DSTATS	771 (\$0303)	128 (\$80

tus variable. Error codes are stored in STATS and loaded into the accumulator and Y register when the handler returns to the CIO. The CIO returns control to you when an error code greater than 127 occurs.

The GET BYTE and special functions are not implemented here and are represented by NOFNT (line 6785). This is simply an RTS which

lowing memory locations:

The command for writing without verification is \$0050, and with verification it's \$0057. The only other variable is the sector number in bytes \$030A and \$030B (low byte, high byte) taken from the variable SECNUM. All other values are supplied by the routine DISKIO.

The second I/O subroutine in lines

7840-7930 accepts either Y or N from the keyboard buffer and loads the accumulator with either a one for Y or a zero for N. Upon returning from this subroutine, a BEQ or BNE tests for the key pressed. The only drawback to this is that the character for the key pressed is not displayed.

These two routines perform I/O consistently between Atari operating systems. SIOV is a vector that always points to the serial bus I/O utility, and the keyboard buffer is always at \$02FC. To get or display a string of bytes from the keyboard, we need a different approach.

#### **SCREEN EDITOR HANDLER**

Both writing to the screen and

dependently of the operating system.

The method for this is included in the initialization routine for the MAKEBOOT handler. Lines 690-1070 first locate the screen editor's Handler Table by searching the Handler Address Table (starting at \$031A) for the E: device.

The two bytes following the ASCII E are the address of the Handler Table, in which bytes 4 and 5 are the address-minus-one of the GET BYTE routine and bytes 6 and 7 are the address-minus-one of the PUT BYTE routine. These addresses are stored in a three-byte jump instruction on lines 8295 and 8320. One is added to each address, so we're ready to do I/O to and from the screen.

# You could use this program to produce your own bootable games or programs that produce a disk menu.

receiving a string from the keyboard can be done via the screen editor handler. Printing to the screen is done by loading the accumulator with the ASCII value of the character to be displayed and doing a JSR to the screen editor's PUT BYTE routine. To get a byte from the screen, do a JSR to the screen editor's GET BYTE routine. Upon return, the ASCII value of the next key pressed will be in the accumulator.

For most Atari operating systems, the screen editor's PUT BYTE routine starts at \$F6A4 and the GET BYTE routine starts at \$F63E. Your program might use these addresses to read and write to the screen. The problem is that these locations aren't guaranteed and may be at different locations in different operating systems. We have to find these handler routines in-

Instead of doing a JSR to a location in the operating system, we do a JSR to either EPUT or EGET. The program is vectored to the true address of the PUT BYTE and GET BYTE routine.

Now that we've established a legal way of using the screen editor to read and write to the screen, we can finish discussing the I/O routines.

To use the subroutine in lines 8140-8270 that displays characters, load the *low* byte of the address of the first character of the string into the accumulator and the *high* byte into the Y register. Then JSR to PRINT.

This continues to display characters until it finds one with the most significant bit set (values greater than 127). If the last character equals 128, then the cursor will remain at the end of that line of text. All values greater than 128 will make the text end with

a carriage return. The only other control character is a carriage return, represented by zero. Lines 8260-8515 give examples of how this routine is used.

The routine called PNUM (lines 7950-7975) displays a two-byte integer as a base 10 number. To use it, put the low byte of the number in \$00D4 (FR0) and the high byte in \$00D5. Then do a JSR to PNUM. The routine uses the floating-point routines found at \$D800 to \$DFFF. IFP converts the integer to a floating-point number in FR0. FASC converts a floating-point number in FR0 to a string in a buffer called INBUFF at \$0580. PRINTE displays the resulting string.

Finally, GETNUM inputs a usergenerated number and converts it to an integer in FR0. This routine also uses the floating-point routines, but it starts with an ASCII string in IN-BUFF. The string is input from the keyboard by doing a JSR to EGET until a carriage return is reached. To avoid most errors, the ASCII value for a zero (\$0030) is put in the first byte in the INBUFF buffer. This means that any character other than a number will return a zero.

#### **USING THE PROGRAM**

MAKEBOOT is written for OS/A + DOS, and will not work with Atari DOS 2. Compile the source code (Listing 1, MAKEBOOT.M65) using MAC/65 or your Atari Assembler/Editor cartridge. If you have the Antic monthly disk, you will find both the source code and the executable file (MAKEBOOT.EXE) already on the disk. (This executable file will NOT run with DOS 2.)

Load the resulting file from DOS. To use the new handler, simply use the COPY command to copy the desired load file to the B: handler. You need a disk to hold the new boot sectors. (It's a good idea to use a freshly formatted disk, and always a good idea to work with backup copies of your programs, just in case.)

The first six bytes of information can be added in several ways. The easiest is to put them in your program before compiling it, as shown in the example below.

100 ;Start of your program

110;

120 \*= (your load address)

130 START .BYTE 0

140 SECCNT .BYTE [LAST-START]/ 128+1

150 LOADAD .WORD START

160 RUNADR .WORD (your run address)

170 INITAD JMP (your program init)

170;

LAST is a label that is added to the end of your program.

If this is impossible or inconvenient, they can be added while the MAKEBOOT handler is running. The first opportunity is before the load file is written to the boot disk. At this

FIGURE 1	Boot Sect	tor Data
Byte #	Bytes	Purpose
0	1	Flag stored at \$0240
1	1	Boot sector count
2	2	Load address
4	2	Run address
6	3	Jump to initialization address

The initialization address can start at byte 6 but for the purposes of this program, a jump instruction is placed here.

point the program asks you for the sector count, load address, run address and initialization address.

If you use this method, you must leave at least six bytes between your load address and the beginning of the boot program for the boot information. If you specify an initialization address, you must leave nine bytes because the initialization address is added as a jump to the address you

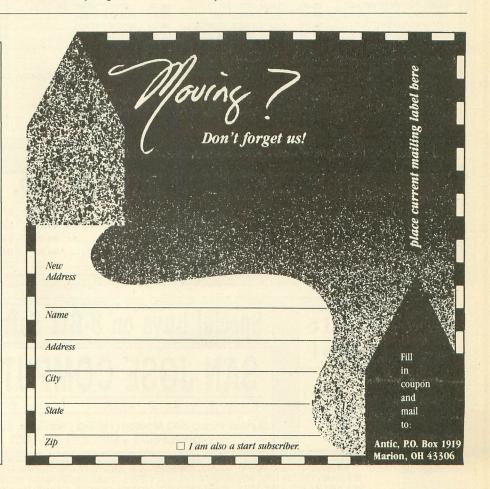

specify and it starts at byte 6.

Finally, after the boot sectors are written, the MAKEBOOT handler gives you the actual sector count, load file run address and load file initialization address. Then it asks you if you want to add them. If you respond with a [Y] to these prompts, the corresponding data will be added to sector 1.

# Exwall

#### Futuristic tank battle for two players.

attle it out for construction space, in this month's Super Disk Bonus. Exwall is a hard-hitting futuristic two player tank game written in assembly language. The program works on 8-bit computers with at least 48K memory, disk drive and two joysticks.

Exwall was written in fast-moving machine language by Andy Barton, who has been contributing to **Antic** since 1984. His programs include *Spelling Flasbcards* (February 1989) and the ever-popular *TYPO II*. His Machine Language Stringer appears elsewhere in this issue.

#### THE SCENARIO

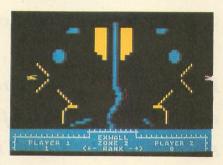

Across eight battle zones, the robot war continues without end. Powerful robots battle it out for building space, over a terrain marked with stone fortress walls and blue rivers and lakes. Massive mobile factories, the robots move about, building and repairing the fortress walls, even as they try to destroy each other.

Your robot carries a cannon that fires explosive shells—but so does your opponent's. In this high-tech slugfest, you must destroy your opponent's fortresses and robot factory without being destroyed yourself. Your ranking reflects your success.

#### **GETTING STARTED**

Don't try to run Exwall directly from the Antic Monthly Disk. Instead, copy EXWALL.EXE to another

#### **Program by Andy Barton**

disk that includes the DOS.SYS file. Use DOS command E to rename EX-WALL.EXE to AUTORUN.SYS. Turn off your computer and remove all cartridges. Place the disk in Drive 1. Hold down the [OPTION] key if you're using an XL or XE. Turn on the computer, and Exwall will load and run automatically.

Plug in two joysticks, one for each player. Use your joystick to move your robot factory up and down, forward, backward and diagonally. You can't move through walls, over water, or into the farthest quarter of your opponent's territory.

To build a wall, move the robot factory to the desired place. Then move back 1 or 2 spaces and stop. A two-layer wall will be built in front of the machine. Construction will stop when the area in front of the machine and within the crane's reach is completed—or when you move the factory.

Press the joystick button once to fire your cannon. Press it a second time to explode the shell. Press and release the fire button quickly, or the shell will explode before you want it to. You can use unexploded shells to knock narrow channels in your own defenses, and then fire through the channels as you hide in the relative safety of your fortress.

You can't move over water but you can build walls at the water's edge. When these walls are destroyed the debris will fill in the water and allow you to move on.

A shell exploding next to a wall will penetrate deeply but not widely. Conversely, if the shell explodes before it reaches a wall it will destroy a wider area but with less penetration.

Crashing your robot into your opponent's will destroy both machines—and possibly get you out of a tight situation. But it won't help your ranking. On the other hand, daring players can significantly enhance their scores by moving in close and firing repeatedly into their opponent's exploding robot.

Your July 1989 Antic Disk—featuring the Exwall Super Bonus game as well as every type-in program from this issue—will be shipped to you within 24 hours after receiving your order. Just phone Toll-Free to the Antic Disk Desk at (800) 234-7001. The monthly disk is only \$5.95 (plus \$2 for shipping and handling) on your Visa or MasterCard. Or mail a \$5.95 check (plus \$2 shipping and handling) to Antic Disk Desk, 544 Second Street, San Francisco, CA 94107.

# TapéTime LabelMaker

Printing your VCR log. By Gary Coppola

apéTime Labelmaker is a label printing utility that will allow you to print the title, speed and time of your favorite videotaped movies or television programs on any Beta or VHS label. I developed the label maker as an add-on to Paul Shannon's *TapeTime* (Antic, January 1989) which determines the amount of time remaining on partially recorded VCR tapes.

When Antic challenged readers to design a patch for an add-on labeler, I thought this should be no problem! A dozen or so lines of code and presto, a labelmaker. Well, after rummaging through all of my VCR tapes and checking out their labels, I realized that in nearly every instance, no two brands provided the same area and location to print in. In fact, even different tape grades of the same brand had different labels. So much for an easy patch.

What evolved after several approaches to the problem was a user-friendly program that automatically selects the print size on the label according to the number of titles you have entered. This allows you to have up to six titles on Beta format labels and up to seven titles on VHS labels. The positioning of the printing area is accomplished with only one user input. It's that easy!

Print VCR labels showing titles, speeds, and times of your favorite movies and shows with TapeTime Labelmaker. A simple modification of Antic's TapeTime program (January 1989), TapeTime Labelmaker will make managing your VCR collection easier than ever. Works on 8-bit Atari computers with at least 48K memory, disk drive and an Epson-compatible printer.

#### **GETTING STARTED**

If you don't already have *Tape-Time* simply type in Listing 2, VCRLABEL.BAS, and be sure to SAVE a copy to disk before you run it.

If you already have TapeTime, the patch can be typed and merged with the original listing. Type in Listing 1, TAPEMOD.LST, check it with TYPO II and LIST it to disk. LOAD the original TapeTime program and then ENTER "D:TAPEMOD.LST". Don't forget to SAVE the merged file back to disk as "D:VCRLABEL.BAS".

Several lines of TapéTime have been rewritten in order to accommodate the labelmaking patch. You'll find the complete TapéTime Labelmaker on this month's Antic Disk, ready to RUN without any modifications or merging required.

#### MAKING A LABEL

When you RUN the modified version of TapeTime the first choice you will have to make is either Do Calculation or Make a Label. If you select Do Calculation you will proceed ex-

actly as in the original TapeTime program.

If you select Make a Label you will next be prompted to choose either Beta or VHS format. After typing your choice, a list of the more popular VCR tape brands will appear onscreen with a column of numbers under the heading of CMAX. This is a suggested value for the maximum number of characters your title should contain in order for it to fit within the allowable space on that brand's label.

After a short time, a scale with numbers ranging from 5 to 35 appears in the message area with room to enter your title right below it. This scale helps you easily determine the number of characters in your title as you are typing it. After entering your first

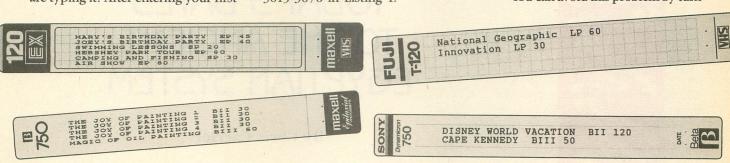

If your brand of tape is not among those in the list, make a trial label on paper to insure that your margin setting and title length are correct. An easy way to find the appropriate margin setting is to hold your label next to the printers' column scale with its left edge on column 0. Then read the column number where you want your printing to begin. This is the margin setting.

Once you determine satisfactory margin settings and title lengths for your particular brand of label, you can replace some of the brands on the list with your own brands and values. This way, you won't forget those numbers the next time you use the program. The lists are located in Lines 3015-3070 in Listing 1.

printer control codes used in this program are Epson codes. If you own a printer that is not Epson compatible you can replace the codes in Lines 3200-3245 with your own printer codes. Each code has a REM statement following it so you know exactly what each code represents. Just look in your printer manual for the proper codes.

When the program enters the printing mode and you input the margin setting, you will notice that the printer advances the label approximately five-eighths of an inch, as a result of the printer receiving the control codes. If you don't take this into account you may have to reposition your label at this point.

You can avoid this problem by turn-

title you will be asked for its speed and time.

This sequence repeats, allowing you to enter up to a maximum of six titles for Beta and seven titles for VHS. If you have less than the maximum, just press [RETURN] when prompted for the next title and you will enter the printing mode.

At this point, insert a label into the printer with the brand name or logo facing to the right. Align the label's left edge with column 0 (on many printers the column scale is located on the tear bar).

#### **HELPFUL HINTS**

Now, turn on the printer and, at the prompt, enter the margin setting. A list of VCR tape brands along with some suggested settings will appear. That's about it—press any key and your label will be printed.

The size of type on the label is controlled by the number of titles you enter. In Beta format, if you have three titles or less, they will be printed in normal-size type. For more than three titles, the print size will be one-half that of normal. In VHS format, four titles or less will be in normal-size type, otherwise you will get the smaller type. If you expect the label to print in the smaller type, I recommend that you use all capital letters in your title for better readability.

After entering your title and speed you are prompted for the program length (in minutes). This was done to keep the same format as in the calculation portion of the program. In the labelmaking portion, however, this is not critical. If you would rather type 2hr instead of 120 (minutes), go right ahead but remember you only have a maximum of three characters. The

ing off the printer's line feed DIP switch when you first place your label in the printer. (My interface has a line feed switch on it also, which makes this process easier.) After entering the margin setting the printer will now receive the codes without moving the label. Turn the line feed switch back on and press any key to print the label.

If you need more room than is allotted on your brand name label, blank VHS pin-feed labels (sorry, Beta owners) are available in a variety of colors from SlideScribe, 7141 Shady Oak Road, Minneapolis, MN 55344.

Gary Coppola of Budd Lake, New Jersey is a senior research chemist for a major pharmaceutical company. He has written two books and has over 75 scientific publications and patents.

Type-In Software

# EGYPT CALENDAR

# CONVERTS TODAY'S DATES TO THE ANCIENT EGYPTIAN SYSTEM

By Chris Carrier

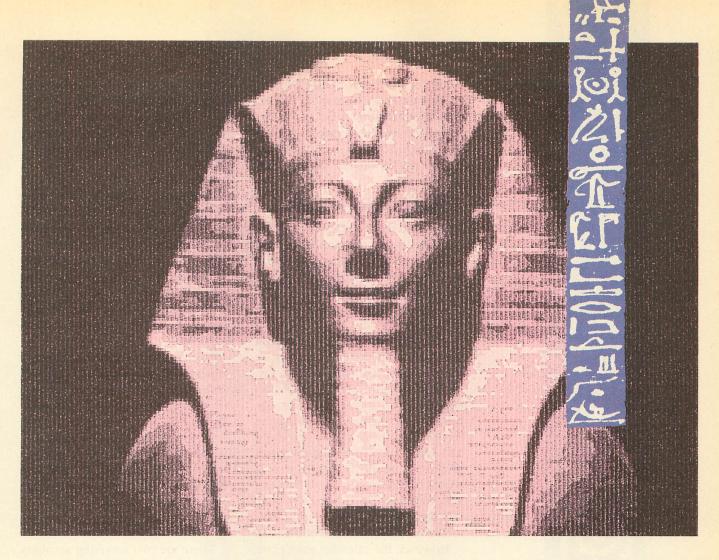

Feel like a Pharoah!
Convert any date
from the Julian
or Gregorian
calendars back to
the calendars
used in ancient
Egypt. This BASIC
program works on
Atari 8-bit computers
with at least 48K
memory.

our Atari can make you an Egyptologist. Egypt Calendar takes any date in the Julian or the modern Gregorian calendars, and gives the equivalent dates in both of the civil calendars used in ancient Egypt, one of which survives even to this day.

Just enter the date, and a screen full of information about that day and year appears. Not only does the program give the original Egyptian calendar date, but the year is given as determined by the reigns of several ancient kings, or by the Alexandrian, Augustan and Coptic calendars. The program can even tell you the day of the week on which that date fell, or the Julian Day number, useful for astronomers.

#### **GETTING STARTED**

Type in Listing 1, EGYPT.BAS, check it with TYPO.II, and SAVE a

copy to disk before you RUN it.

The program will then ask you to input a date. If the date is between 1582-1923, you will be prompted to specify whether the date uses the Julian or Gregorian calendar. The Gregorian calendar began in 1582 A.D., but the last nation to switch from Julian to Gregorian (Greece) did not do so until 1923.

Then press [RETURN] to see how your date translates. At the top of your screen the date you entered will be displayed, followed by the Julian Day Number. Used by chronologists and astronomers, this number simply tells you how many days have passed since January 1, 4713 B.C. (JD #0).

The original Egyptian calendar date follows, with the year as determined by eight different eras. At the very bottom of the screen is the date of the Sothic Rising, the astrological phenomenon used by the ancient Egyp-

tians to track the actual, as opposed to calendar, year.

During the first couple of millenia of the calendar's existence, the months had no names, but were simply referred to as the first, second, third. . .month of their season.

#### **EGYPTIAN DATES**

The ancient Egyptians, among their other accomplishments, were probably the first people in the history of the world to discover the number of days in a year down to the nearest integer.

The original version of the Egyptian calendar had a week of 10 days, a month of 3 weeks or 30 days, a season defined as 4 months or 120 days, three seasons equaling 360 days, which were followed by five unnamed epagomenal, or "outside the calendar," days to total 365 days in a year.

The year began with the season of Akhit (Flood, as in Nile River), followed by Perit (Winter) and Shemu (Summer). Egypt Calendar gives this date thus: Shemu 2-14 for the 14th day of the second month in the summer (Shemu) season. The five epagomenal days are treated by the program as a five-day, fifth month of Shemu. Because a tradition developed that any work done on the epagomenal days was unlucky, the ancient Egyptians ended their year with a five-day festival.

The great advantage of the Egyptian calendar is that it was easy to use—it survived in daily use for more than 3,000 years. Astronomers and historians used the calendar for convenience of chronology as late as the 16th century. France tried a version of it shortly after the French Revolution, in the late 18th century. This calendar has even drawn praise from

a 20th century astronomer (Neugebeuer, "A History of Ancient Mathematical Astronomy") for being the "most sensible of all calendars used by mankind", with its easy-to-use 10-day weeks, 30-day months, and 365-day years.

#### **CORRECTIONS NEEDED**

The great disadvantage of Egyptian calendars is that the number of days in the year is not 365, but rather 365.2422 days in a tropical year (the cycle of the seasons) or 365.2564 days in a sidereal year (one orbit of Earth with respect to the stars).

Therefore, the Egyptian calendar ran about 1 day fast every 4 years, so if an annual event occurred on, say, Akhit 1-1 in a given year, it would occur on Akhit 1-2 after four years, Akhit 1-3 after eight years, during the second month of Akhit after about 120 years, and eventually, the event would go around the entire year. It would have been obvious within, say, 100 and certainly before 200 years that the calendar needed to be corrected for the true length of the year.

However, the calendar wasn't corrected for thousands of years, but the Egyptians invented a second new year. The "true" year, as opposed to the calendar year, began when Sirius, the brightest star in the sky (except for our own sun) appeared for the first time in the predawn sky after having been behind the sun and invisible. Because the Egyptian name for Sirius is "Sothis," this annual event is called the Sothic Rising.

On July 20, 139 A.D., a Roman living in Egypt by the name of Censorinus observed a Sothic Rising on the first day of the Egyptian year. He furthermore stated that as the Julian calendar contained 365.25 days, and the Egyptian 365, that 1460 Julian years equaled 1461 Egyptian years, and he labeled this the "Sothic Cycle," or the "Great Year" of the Old Egyptian calendar, now known as the "Julian Sothic Cycle."

Since Censorinus' time the exact

length of the sidereal year has become known, and the true Sothic Cycle is 1422 Old Egyptian years long. The next time a Sothic Rising coincides with Akhit 1-1 will be on August 27, 2985 A.D.

Also of note is the fact that the Sothic Rising occurs in the Julian calendar about 1 day later every 150 years, and in our Gregorian calendar, 1 day later every 72 years. This is because of the precession of the equinoxes, the same phenomenon which makes Polaris the North Star in our lifetimes and Thuban the North Star during the building of the Great Pyramid.

Although any estimates as to exactly when the Egyptian calendar began to function are only educated guesses, Sothic Risings on Akhit 1-1 occurred in 1282-85 B.C., 2706-09 B.C., and 4130-33 B.C. The program designates the last mentioned date as Cycle #0, and it is believed that the calendar may have started regular use about the beginning of Cycle #1.

#### **REIGNS AND ERAS**

There are two surviving accounts of ancient Egyptians observing a Sothic Rising—during the reigns of Senworset III and Amentohep I. Because of this, we can calculate the exact year their reigns began, and this date is given in the program; in ancient Egypt, and in fact in most of the world's monarchies, the year used is the number of years since the accession of the current monarch.

In the second century A.D. the Greek astronomer Ptolemy compiled a "Canon of Kings," a reference book that attempted to standardize the dates of the reigns of the monarchs of various empires. As his reference, he used the 365-day Egyptian year because of its convenience and established a year 1 at the crowning of the Babylonian king Nabonassar.

The Nabonassarian Era is the most common one used in connection with the Old Egyptian calendar, although it was never used by either the Egyptian government or its subjects. (In fact, the World Almanac 1989 gives in "Chronological Cycles" the opening of the Nabonassarian Year 2738 on April 26, 1989—a fact that can be checked using Egypt Calendar.)

When Augustus Caesar conquered Egypt, shortly after the Roman Empire adopted a 365.25 day year, he decreed that a 366th day be added to the Egyptian calendar in every fourth year, thereby setting up a new 365.25 day calendar with an Augustan Era (from Augustus' accession) and an Alexandrian Era (from Rome's conquest of Egypt).

After Augustus' death, however, the new calendar went ignored for almost 300 years, until the Coptic Christian Church in Egypt decided to start using it, with an era beginning with the reign of the then-current Roman emperor, Diolectian. Since Diolectian is primarily remembered for persecution of and atrocities against Christians, the Coptics refer to their era, which they use even today, as the "Era of Martyrs." The year 1706 of the Coptic Era of Martyrs begins on Sept. 11, 1989.

Egypt Calendar gives the date in the revised 365.25-day Egyptian calendar, and as names for the months were in use by the time of the reform, these month names are used instead of the season and month number. The year in the New Egyptian calendar begins on August 29 or 30 in the Julian calendar, and between 1900 and 2099 A.D. in the Gregorian calendar, on September 11 or 12. The Alexandrian, Augustan, and Coptic eras are all given by the program.

This program was inspired by the chapter on the Egyptian calendar in O. L. Harvey's "Calendar Conversions by way of the Julian Day Number."

#### LIST OF VARIABLES

CAL\$—the calendar in which the date is being inputted, either Julian or Gregorian. Anyone entering a date between 1582-1923 will be prompted for the calendar they want.

ENSEASON\$—The season of the year, in the original Egyptian calendar. EMO—The number of the month in the season in the original Egyptian calendar.

EBM—The day of the month in the original Egyptian calendar.

D\$—The day of the (seven day) week.

M\$—The month of the year in the Julian or Gregorian calendar.

DATE—The day of the month, Julian or Gregorian.

IYEAR—The number of the year, Julian or Gregorian.

ERA\$—A.D. or B.C.

JDAY—Julian Day Number, used by chronologists and astronomers, and is a linear count without end. JD #0 was January 1, 4713 B.C.—in the late 20th century A.D., the number is between 2440000 and 2450000.

JSC—Julian Sothic Cycle of Censorinus. 1461 original Egyptian years long.

TSC—True Sothic Cycle. 1424 original Egyptian years long.

EY—Number of the original Egyptian year in the current Julian Sothic Cycle.

TEY—Number of the original Egyptian year in the current True Sothic Cycle.

SENWORSET3—Number of original Egyptian years since the coronation of Senworset III.

AMENHOTEP1—Number of original Egyptian years since the coronation of Amentohep I.

NABONASSAR—Number of original Egyptian years since the coronation of Nabonassar.

CY—Year of the Coptic Era of Martyrs, expressed in the New Egyptian calendar with a 366th day every 4th year.

ENMONTH\$—The month of the Egyptian year, expressed in the 365.25 day New Egyptian calendar.

CBM—The day of the month in the New Egyptian calendar.

ALEXANDRIAN—The day of the month in the New Egyptian calendar, counting from Augustus' conquest of

Alexandria and his attempt to institute a 365.25 day calendar in Egypt.

AUGUSTAN—The day of the month in the New Egyptian calendar, counting from year 1 of Augustus' reign as Emperor of Rome.

SRMONTH\$—The Julian or Gregorian month in which Sirius makes its first appearance in the early morning (the Sothic Rising) just before dawn, after having been invisible for a month or so because it was above the horizon during daylight hours only.

SR—The day of the month on which the Sothic Rising occurs.

Chris Carrier lives in Sacramento, California. His interests include astronomy, chronology and games. His articles have appeared in USA Today and the Barrow Sun, the northernmost newspaper in North America. This is his first appearance in Antic.

# Red Squares

Challenge for your mind and your reflexes. By Marc Abramowitz

Are you sick and tired of shoot-'emup games? Do the words "Space Invaders" drive you crazy? Well, if you're tired of senseless violence, ringing ears and joystick-cramped hands, try Red Squares, a challenging strategy game that challenges your mind and reflexes.

Red Squares is based on an imaginative Russian computer game. A popular American version has been released for several makes of personal computers including the Atari ST—but not for the 8-bit Atari.

But now this oversight is remedied. Red Squares lets you play this colorful and exciting new game on your 8bit Atari. The game features 50 speeds and other options for added challenge.

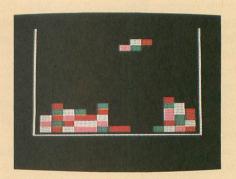

#### **GETTING STARTED**

Type in Listing 1, SQUARES.BAS, and check it with TYPO II. Be sure to SAVE a copy before you RUN it.

If you have trouble typing the special characters in lines 100 and 8010, don't type them in. Instead, type Listing 2, check it with TYPO II and SAVE a copy. When you RUN Listing 2, it creates these hard-to-type lines and stores them in a file called LINES.LST.

To merge the two programs, LOAD "D:SQUARES.BAS" and then ENTER "D:LINES.LST." Remember to SAVE the completed program before you RUN it.

Various shapes, all made of four

This colorful strategy game, adapted from the popular Russian import, challenges both your mind and reflexes. This BASIC program works on 8-bit Atari computers with at least 48K and disk drive.

squares, fall into a pit. The object is to move and rotate the shapes, guiding them into position at the bottom of the pit. Whenever the shapes fill a complete line across the bottom of the pit, that line disintegrates, and the pieces above move down. The game is lost when the pieces are piled up all the way to the top of the pit.

You get a certain number of points

for completing a line, depending on how close it is to the top of the pit. The closer the line is to the top of the pit, the more points you get. You also score one point for each shape that falls into the pit. Even if you can't complete many lines, you should try to survive as long as possible.

When you first RUN Red Squares, press [START] or the joystick button

to reach the options screen. Move the joystick up and down or press [SE-LECT] to change the speed, which ranges from 1 to 50. As you play, the speed increases gradually, so don't start at too high a speed.

Moving the joystick right and left or pressing [OPTION] lets you add extra challenge to the game, by starting the game with one to ten layers of randomly-placed pieces in the bottom of the pit.

#### **FALLING SQUARES**

Once you've selected speed and height, press [START] or the joystick button to begin the game. The pit will appear, and pieces will start falling from above, one by one.

Move pieces right or left using the joystick, or by pressing [J] and [L]. To rotate a piece 90 degrees, press the joystick trigger, or [K]. Pieces may be rotated several times—if the shape changes with such rotation. The square doesn't rotate, since the shape would remain the same.

Try to leave as few gaps as possible when landing pieces. The more lines you complete, the more room you'll have for future pieces—and the more you manage to get into the pit, the higher your score.

These rules are simple, but play can be challenging. With a little practice, you'll know which pieces will fit which spaces best—but the piece you need most may take its time about arriving. As the pieces fall faster and faster you'll find yourself struggling to place each piece just so. It takes intense concentration and some sharp thinking to truly master the falling squares.

Marc Abramowitz is a Freshman at Port Richmond High School in Staten Island, New York. Besides computers, his interests include playing the guitar and fantasy role-playing games—particularly Teenage Ninja Mutant Turtles and Advanced Dungeons and Dragons. This is his first appearance in Antic.

# Light show with a hidden message.

By Ernie Negus

any people who use computers are highly analytical thinkers. There is nothing wrong with that, but new ideas that are difficult to prove seem a little off-the-wall to them. I myself was very skeptical about subliminal perception. I simply did not believe the claims that some people made about it. After reading a book on the subject, I decided to try out my own experiment with subliminal messages.

Flash! is one of my experiments, a short machine-language program that lets you enter a message, which is then flashed on the screen in a series of dots.

#### **GETTING STARTED**

Type in Listing 1, FLASH.BAS, check it with TYPO II and SAVE a copy before you RUN it. When RUN,

FLASH.BAS creates a machine language program called FLASH.EXE. Antic Disk owners will find FLASH.EXE on the monthly disk.

Don't try to run Flash! from the Antic Monthly Disk. Copy FLASH.EXE to another disk that has the DOS.SYS file on it. Then rename FLASH.EXE to AUTORUN.SYS.

Turn your Atari off and place your Flash! disk in drive 1. Now, turn on your Atari and Flash! will automatically load and start.

#### CONVINCING EXPERIENCE

My first experiment with subliminal perception convinced me that it worked. At the time, about two years ago, I upgraded my 130XE to 1Mb of memory. I was also running a 24-hour bulletin board.

To show off the power of a 130XE with one megabyte, I wrote a "Spin-

Give yourself a subliminal boost—or test the power of subliminal messages on your family and friends with Flash! This BASIC program creates a machine language program that works on 8-bit Atari computers with at least 48K memory.

ning World" demo program. Using a map-generating program, I created 120 maps of the globe, incrementing the longitude three degrees for each.

I then loaded these maps into the one megabyte of memory and wrote a program to switch the banks during vertical blank time. In this way, I could show the 120 different maps in rapid succession, and the effect was quite impressive. I even had paddles to control the speed, and if the trigger was pressed I could use the paddle values to determine the frame displayed. Rotating the paddle control yielded a very weird effect, as the globe would eerily rotate along with it.

I was working at a computer store, demonstrating my program at various trade shows. It was quite a popular display. As an experiment, I added another frame that would flash for a few milliseconds just before the first frame when the globe was spinning at full speed.

At the time, my BBS was very inactive. I was lucky to get three or four calls a day. So naturally my subliminal suggestion was, "Call BEE-CATS BBS!" written in huge letters on the extra frame.

The effect was a slight flickering of the screen when the demo was running. The flicker was barely perceptible and far too fast to read no matter how hard you looked.

The demo with its subliminal message ran at a trade show for three days. The night of the first day I had fifty calls on my BBS. The next day, I had over 200!

Talking with some of the callers (most were already logged in, but hadn't called for a long time) I found they all had been to the trade show. Not only that, most did not even know that I had written the spinning world demo! It was this experience that caused me to believe wholeheartedly in subliminal perception.

#### **HOW FLASH WORKS**

Flash! is another experiment in subliminal suggestion. Based on a concept by artist and engineer Bill Bell, it works on the phenomenon of the eye's perception of light and the way the subliminal mind can interpret the patterns from the eye.

After you run the program you will be prompted for a phrase. Enter a single word or a short phrase. For the best results, keep the phrase as short as possible, with not more than four words. After that, the screen clears and a column of eight boxes will begin to flash rapidly on the screen.

Most people who see this will just think it's a pretty display. If they try to concentrate on the flickering boxes to get any meaning they will probably think even less of it. But when they look away and start thinking about something else, the words you typed may suddenly appear in their imagination.

To understand how the program works, visualize one of those electric news signs, like the one in New York's Times Square, where words travel across a panel. The sign contains several columns of bulbs that turn on and off in a special sequence to pro-

duce the moving message effect.

Now visualize just looking at one of the columns of lights. After a certain amount of time, the whole message gets scrolled through that one column. But it looks like just a bunch of flickering lights.

Your subliminal mind is able to perceive the message being scrolled through that single column of lights, but your conscious mind cannot comprehend it as a message. It is only when you look away, when you may finally get the message coming through.

This makes Flash! a great program for developing your subconscious mind. For example, if you want to lose weight, use the phrase, "I will be thin" on Flash!. If you are trying to develop a more positive attitude try "I am happy." Try to avoid negative words such as "not" or "no" or "won't" — these words tend to confuse the subconscious mind and will often produce the opposite of the desired effect.

To exit Flash! while it is displaying your phrase, just press any key. To slow down the message, press the [SE-LECT] key and release it several times. To speed it up, press the [OPTION] key several times. The audible click that occurs happens at the end of the phrase, just before the message is recycled through.

Ernie Negus is a longtime contributor to Antic. Currently be lives in Botbell, Washington, working as a technician on stateof-the-art ultrasound equipment.

# SOFTWARE LIBRARY

#### TYPING SPECIAL ATARI CHARACTERS

The Atari Special Characters and the keys you must type in order to get them are shown below:

For [CONTROL] key combination, *bold down* [CONTROL] while pressing the next key. For inverse [CONTROL] [A] through [CONTROL] [Z], press the [2] key—or [本] on the 400/800—then *release* it before pressing the next key. (Press [2] or [本] again to turn off inverse.) For [ESC] key combinations, press [ESC] and then *release* it before pressing the next key.

Carefully study the chart above and pay close attention to differences between lookalike characters such as the slash key's [/] and the [CONTROL] [F] symbol [ ].

#### TYPO II AUTOMATIC PROOFREADER

TYPO II automatically proofreads **Antic**'s type-in BASIC listings. Type in the listing below and SAVE a copy to disk or cassette. Now type GOTO 32000. At the prompt, type in a single program line **without the two-letter TYPO II code at the beginning**. Then press [RETURN].

Your line will reappear at the bottom of the screen. If the TYPO II code does not match the code in the magazine, then you've mistyped your line.

To call back a previously typed line, type [\*], then the line number, then [RETURN]. When the completed line appears, press [RETURN] again. This is how TYPO II proofreads itself.

To LIST your program, press [BREAK] and type LIST. To return to TYPO II, type GOTO 32000. To remove TYPO II from your program, type LIST "D:FILENAME",0,31999, then [RETURN], then NEW, then ENTER "D:FILENAME", then [RETURN]. Now you can SAVE or LIST your program to disk or cassette.

                         C=C+1:GOTO 31992:DATA 4,LIST,10
VG
        GOTO, 11, GO TO, 12, GOSUB, 13, TRAP, 27, THEN, 30, ON, 35, RESTORE
```

Recently I purchased an unprotected BASIC program and found it was mostly "spaghetti code" — a mindless collection of GOTO, GOSUB, and TRAP statements! I immediately decided to re-write it, but it was too long and too complicated.

I was deathly afraid to change any lines, fearing another line would try to call it! Because it was a BBS program, I couldn't have some user get a READY prompt while I wasn't home!

In my typical fashion of trying to write programs which I understand nothing about, I seem to have succeeded with GOTOLIST.

GOTOLIST will search any BASIC program and find all line numbers referenced by other program lines. For example, GOTOLIST would save line 10 if it is: 10 GOTO 100

Although GOTOLIST is small, it's not stupid. If it encounters the following line:

10 GRAPHICS 0:? "HELLO.";:INPUT A\$:IF A\$ = "NO" THEN ? "OK":GOTO 100

all it saves is: 10 GOTO 100.

Type in the listing below, GOTOLIST.LST, check it with TYPO II, and *list* a copy to disk with the command:

LIST "D:GOTOLIST.LST",31990,31999

Now type NEW and LOAD a copy of that favorite program you've been dying to modify but are afraid of destroying. (Never modify your original copy—you're just asking for trouble!)

First, make sure your program doesn't use any line numbers above 31990. Then ENTER "D:GOTOLIST.LST" [RETURN] and type GOTO 31990. In a short while (It takes about a minute to check your program, so bring a good book if your program is long) GOTOLIST will display its list of lines which call other program lines.

If you want to see the list again, type PRINT A\$, or LPRINT A\$ for a printout. For best results, put your printer in 76-column mode by typing:

LPRINT CHR\$(27); CHR\$(81); CHR\$(76)

Your printer may require a different code—consult your printer manual.

Now, before you change any line, just a glance at the list will insure nothing is trying to use that line for other purposes! If something is, however, just one more glance and you'll see which line is the culprit, and you can modify to your heart's content!

Antic pays \$25 for every original and exclusive Tech Tip submission that we publish. Send your 8-bit or ST disk and printout to: Antic Tech Tips, 544 Second Street, San Francisco, CA 94107. Tech Tips welcomes very short programs that demonstrate the Atari's powers, simple hardware modifications, or useful macros for popular software.

#### TWO NEW, SENSUOUS GAME TITLES

### Look out, Indiana Jones! Step aside, Bogie! Crash Garrett's in town!

Don't wait 'till Sunday to catch-up on your favorite action comic — play *CRASH GARRETT* instead!

No other adventure game is quite like this...

Let ace flyer *CRASH GARRETT* escort you through Hollywood in the '30s to rescue sultry, sexy gossip columnist, Cynthia Sleeze, from the sinister Nazi

mastermind Baron von Engel Krul and his cronies. Help CRASH stop this perverse Nazi spy-ring from kidnapping glamorous, American beauties to use as

breeding stock for an Aryan race of

superhumans. Be the voice in CRASH's head as he encounters adventure after adventure with a whole group of wacky, depraved characters including Caleb Thorn, psychoanalyst

to the stars, and Lotta Linebacker, a female wrestler who knows what she wants from a man!

CRASH GARRETT is style and pizzazz—an animated comic book with a slick, continential look. It's about as much

terror, intrigue and suspense you'll want from any game!

## Play Stir Crazy With Bobo—

Your idea of "doing time" will definitely change!

Had a little too much violence lately? Still want fun and action? Well, grab your joystick and join poor Bobo in six of the most graphically amusing adventure games ever on disk.

Bobo's in prison—INZEESLAM-MER—where he spends most of his time performing menial chores and planning his escape. Bobo's no penal pushover!

Bobo starts his day feeding porridge to hungry, irritable prisoners. Don't

let him get too befuddled, or else he'll end up with the porridge bucket on his head.

K.P.'s next. Speed is the key here. Don't let Bobo get buried underneath a pile of spuds!

An exhausted Bobo tries to catch up on his beauty sleep, but

is constantly interrupted by the relentless snoring of his cell mates. Finally Bobo makes his escape and hurtles off into the sunset, right onto electric train cables. Bobo needs some pretty fancy footwork to avoid the pulsating current!

Available for Atari ST\* and Amiga® Computers at your favorite store. To order by phone, call 800-234-7001.

CRASH GARRETT— \$3995
STIR CRAZY with Bobo— \$349

Terrific Software, 544 Second St., San Francisco, CA 94107 (415) 957-0886
